IBM Cloud Workshop

Tal Neeman
Developer Advocate
IBM

IBM Developer

IBM

Hi, I’m Tal

I’m a developer advocate for IBM.

I participate in meetups, hackathons, webinars and write articles about technology for IBM and other organizations.

IBM Startup & Developer - Tel Aviv

Warning: I am a lowly developer

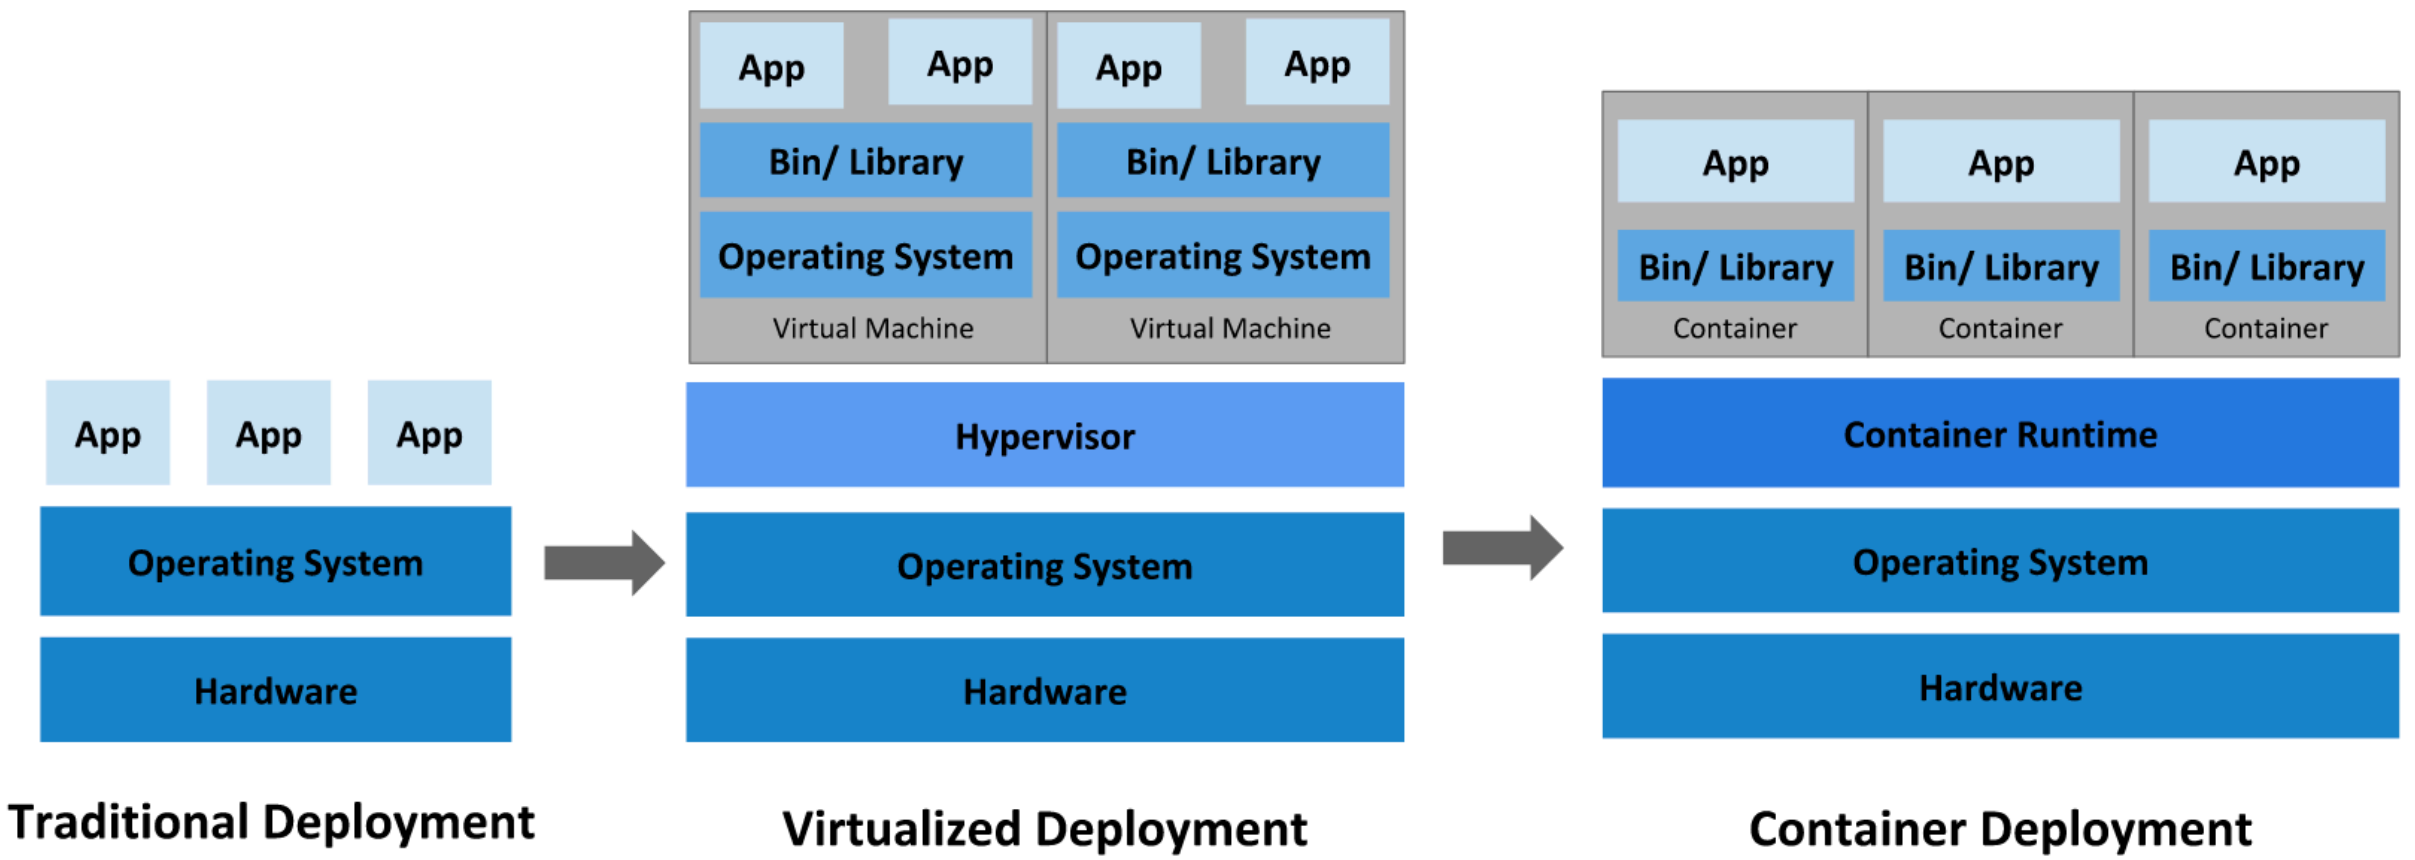
What are Containers?

OS level virtualization

- Isolate user space instances on a single host machine
- Gives isolated view of processes, user space and file system for user owner
- Share host Linux kernel
- A self-contained sealed unit of software
- Contains everything required to run the code

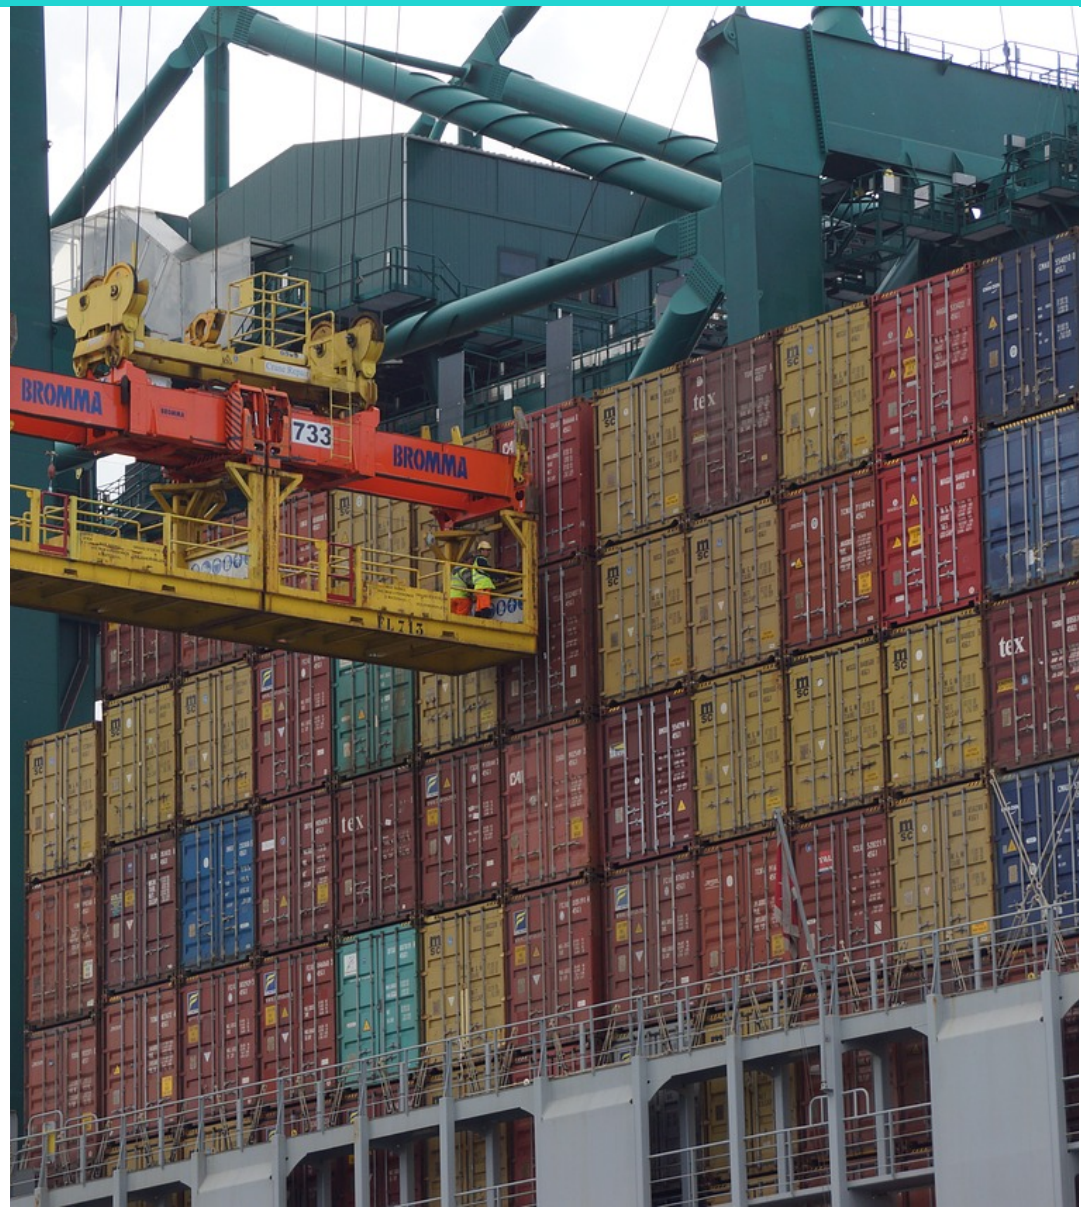
A Container Includes :
Code, configs, Processes, Networking, Dependencies, OS (just enough)

VM vs Container



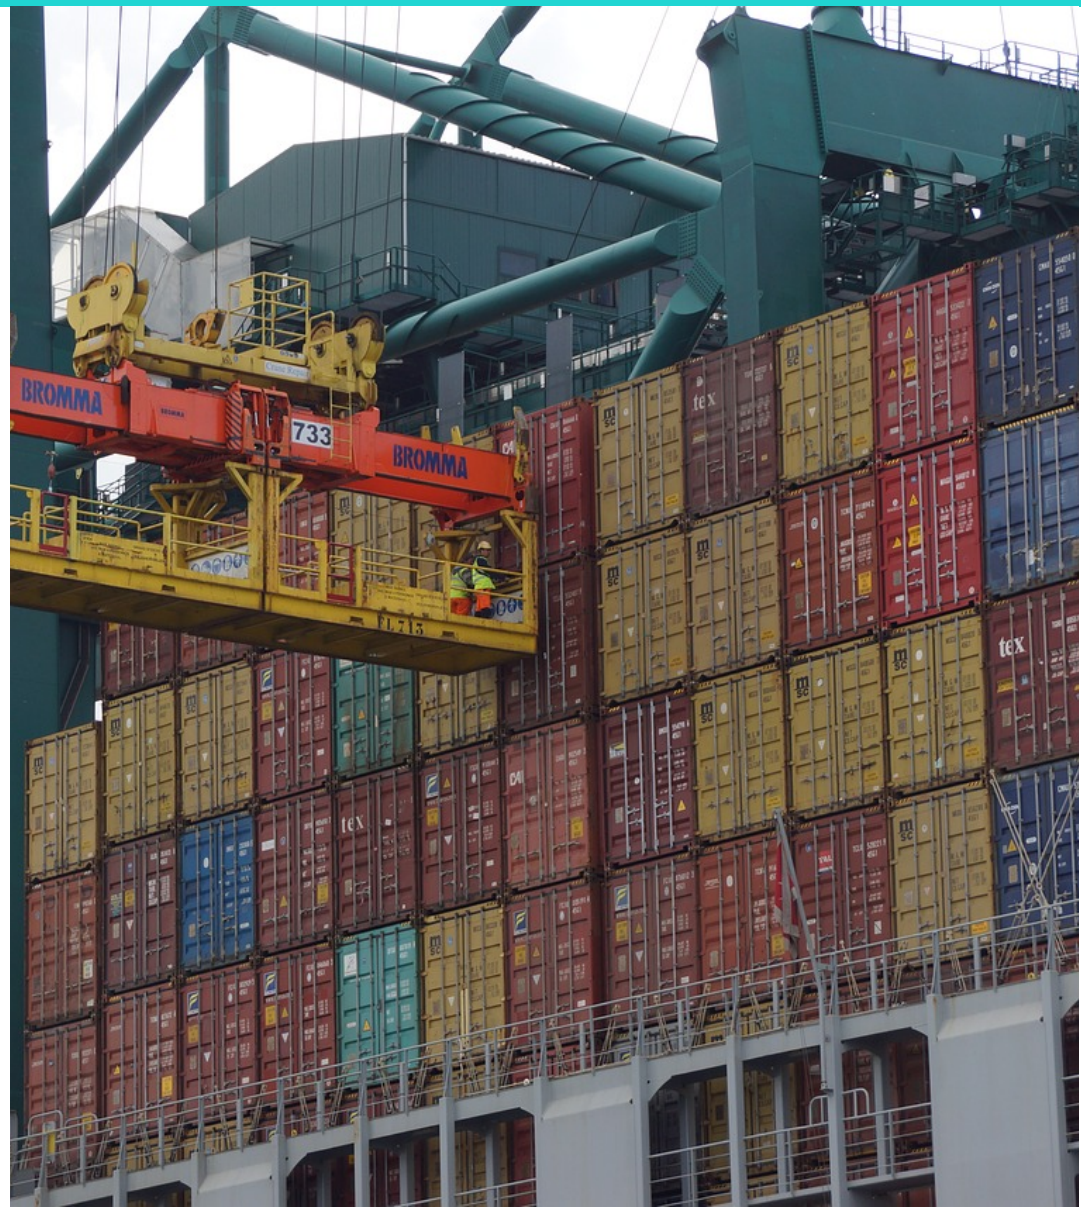
Containers: Dev vs Ops

DEV	**OPS**
Code	Logging
Libraries	Remote Access
Config	Network Config
Runtime	Monitoring
OS	



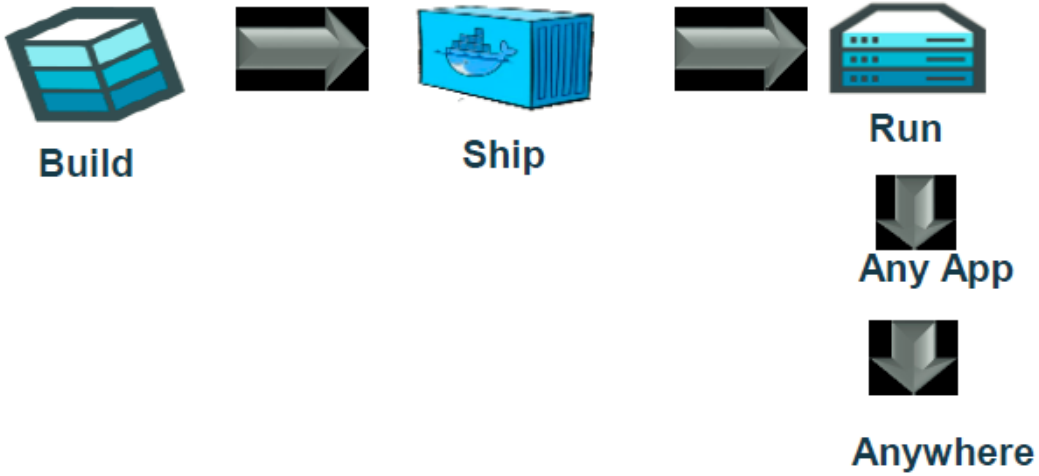
Why Containers?

- Agile
- Continuous Deployment
- Dev and Ops
- Observability
- Consistency
- Management
- Microservices
- Resource Isolation
- Resource Utilization
- Portable
- Easy to manage
- Containers provide “just enough” isolation
- Immutable



What is Docker?

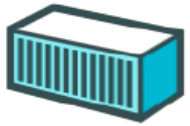
Docker is the world's leading containerization standard platform



Docker is a platform for developing, shipping and running applications using **container** virtualization technology.

What is Docker?

Image
Template to use for creating containers. Snapshot of Read-Only stored in Docker Hub。



Container
Basic unit on which application service runs。

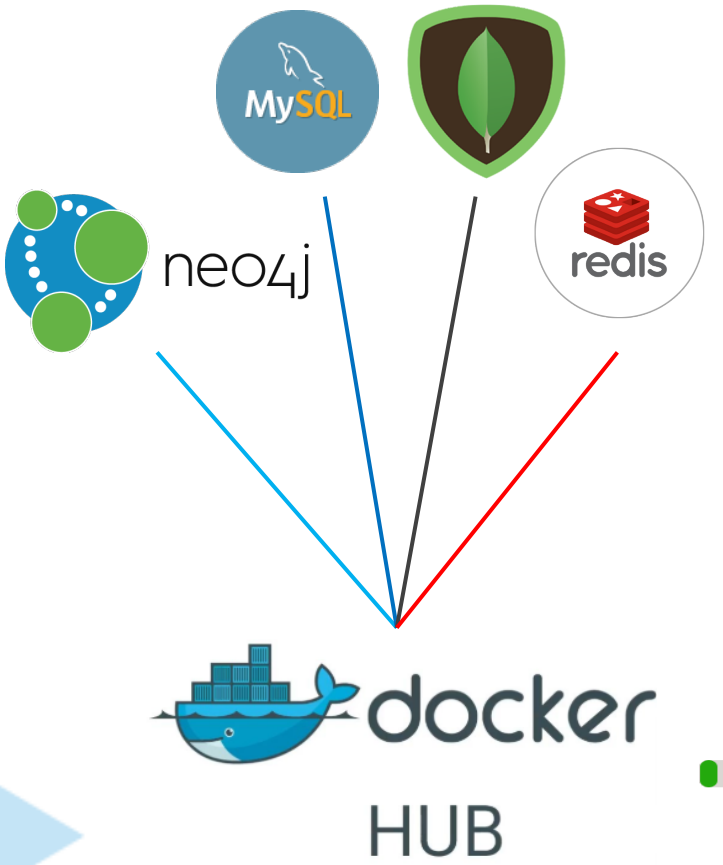
Docker Hub
Store, distribute and share images of containers.
Establish and use in SaaS or enterprise.

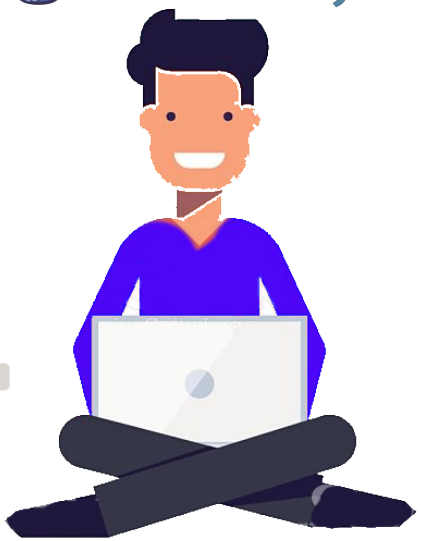
Docker Repository
Pulling an image from Docker Trusted Registry is the same as pulling an image from Docker Hub or any other registry. Since DTR is secure by default, you always need to authenticate before pulling images.。

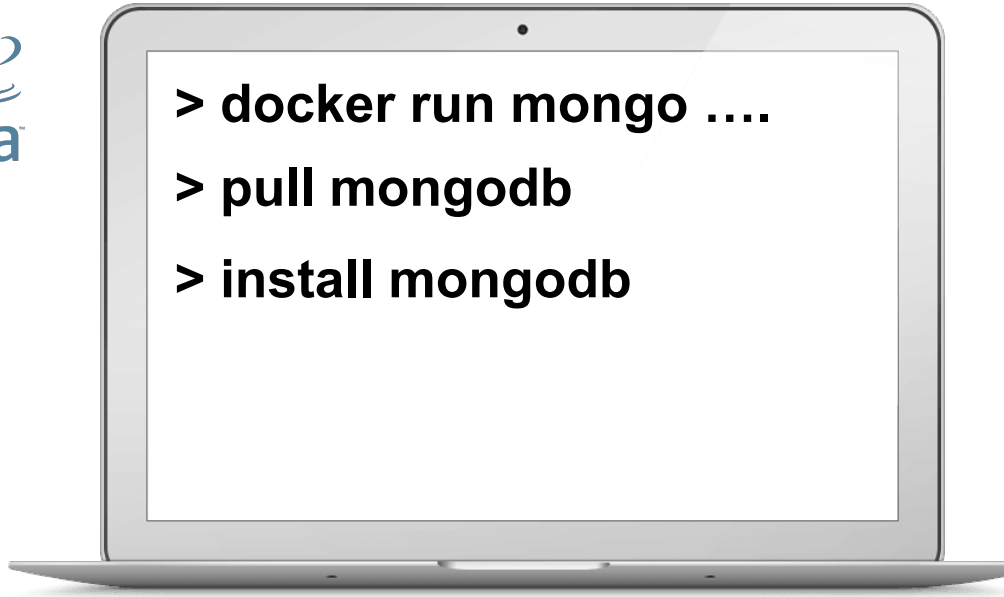
Docker Engine
A program for creating containers and running them.
Run on a physical server or virtual machine.
User can operate with command。

Docker :

Docker makes it really easy to install and run software without worrying about setup or dependencies

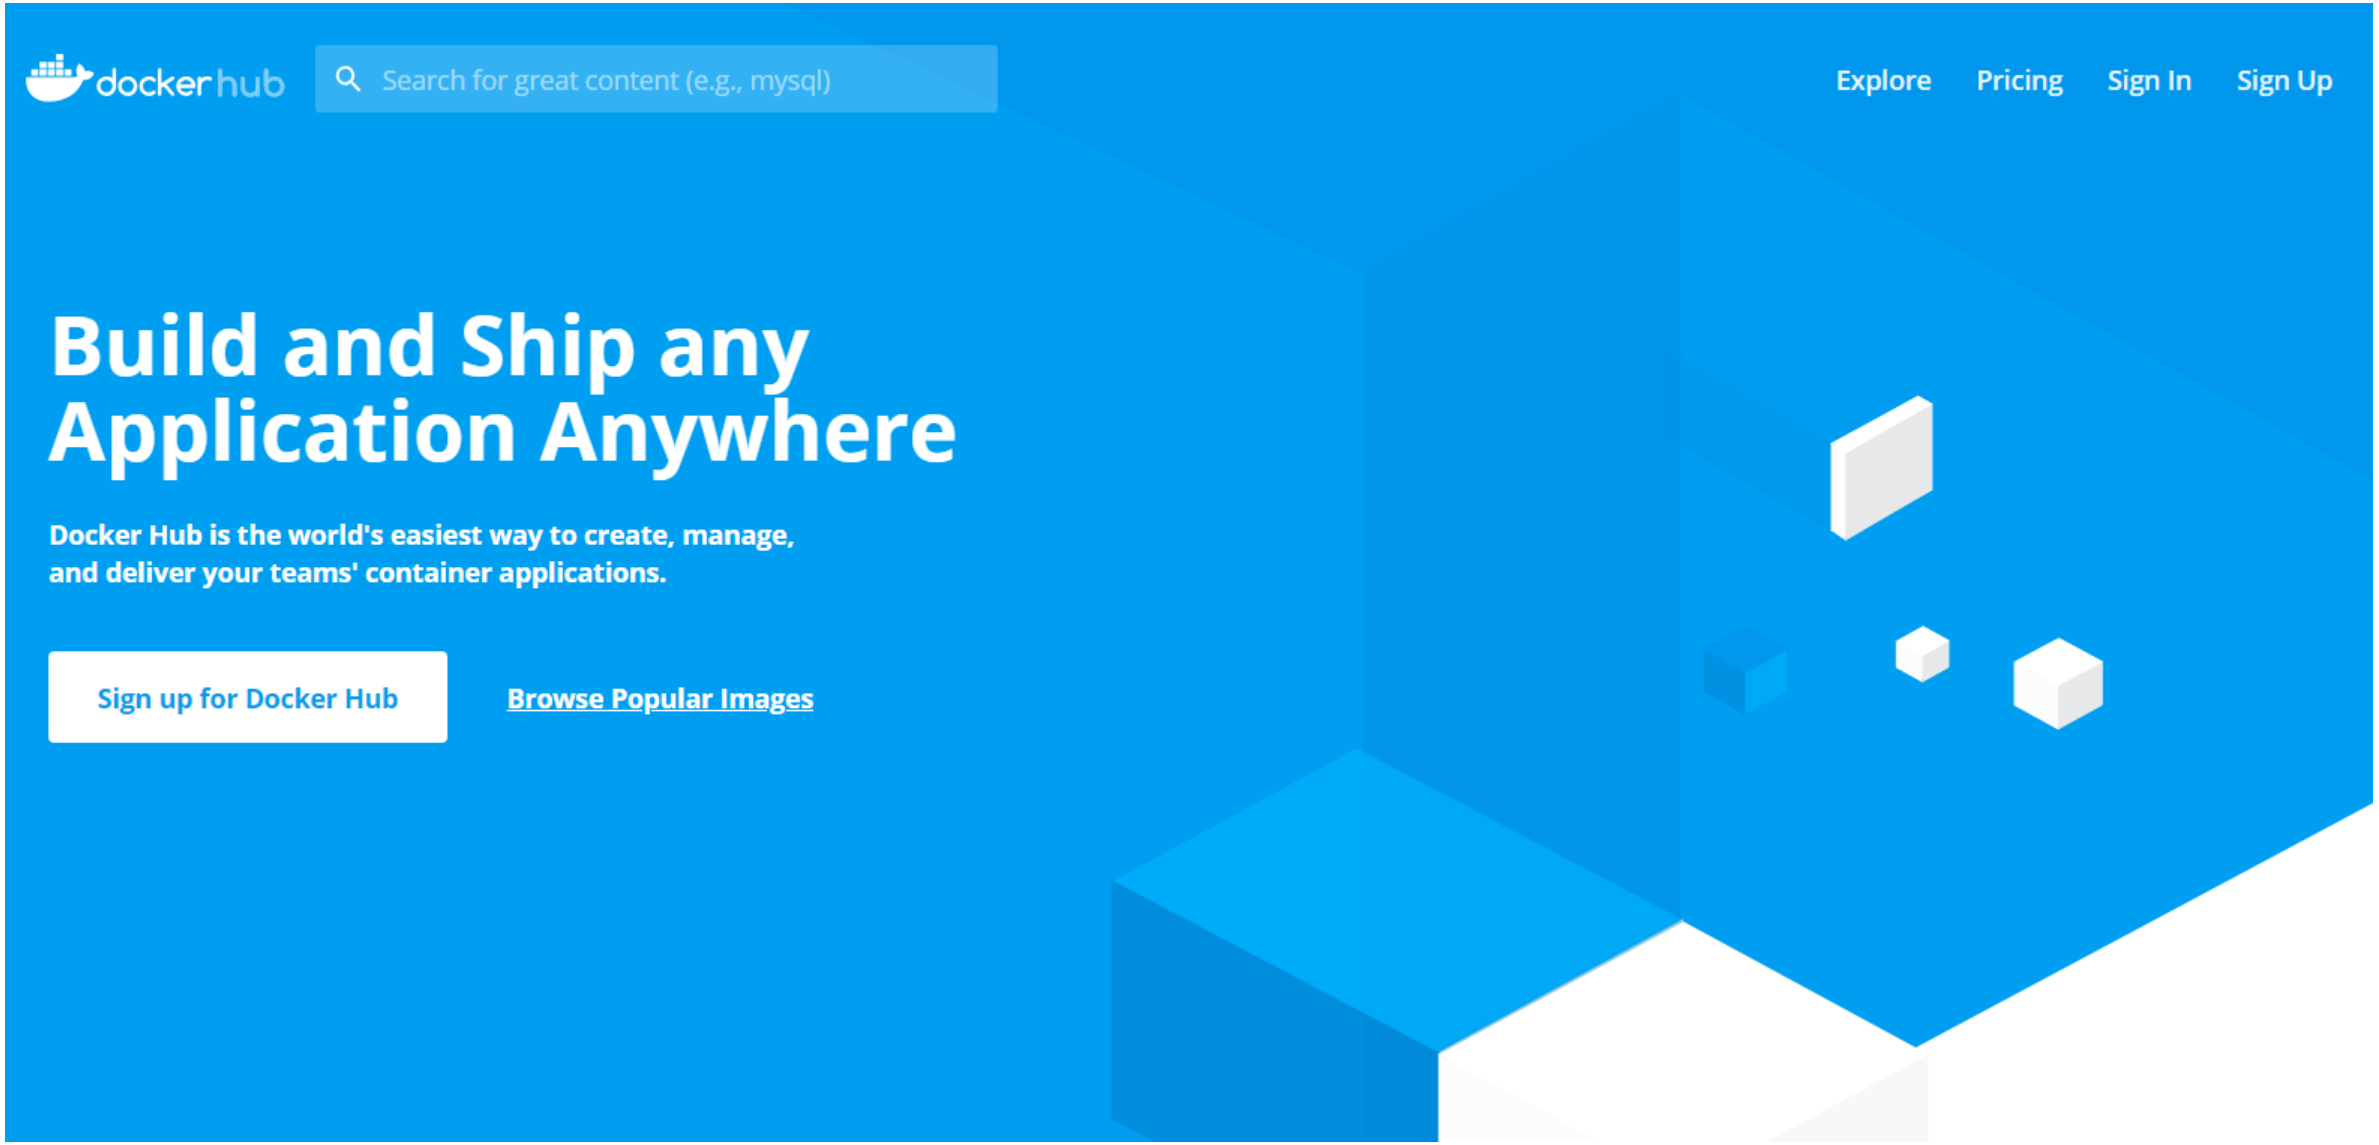




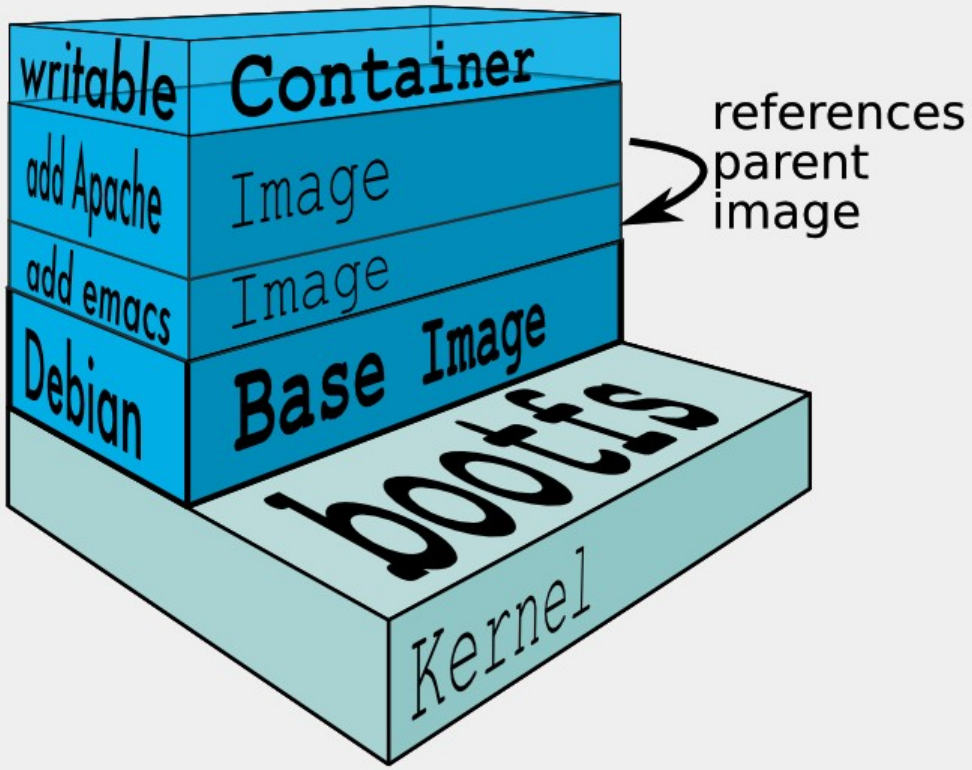


Common images available on the cloud

hub.docker.com



Layers of Docker container



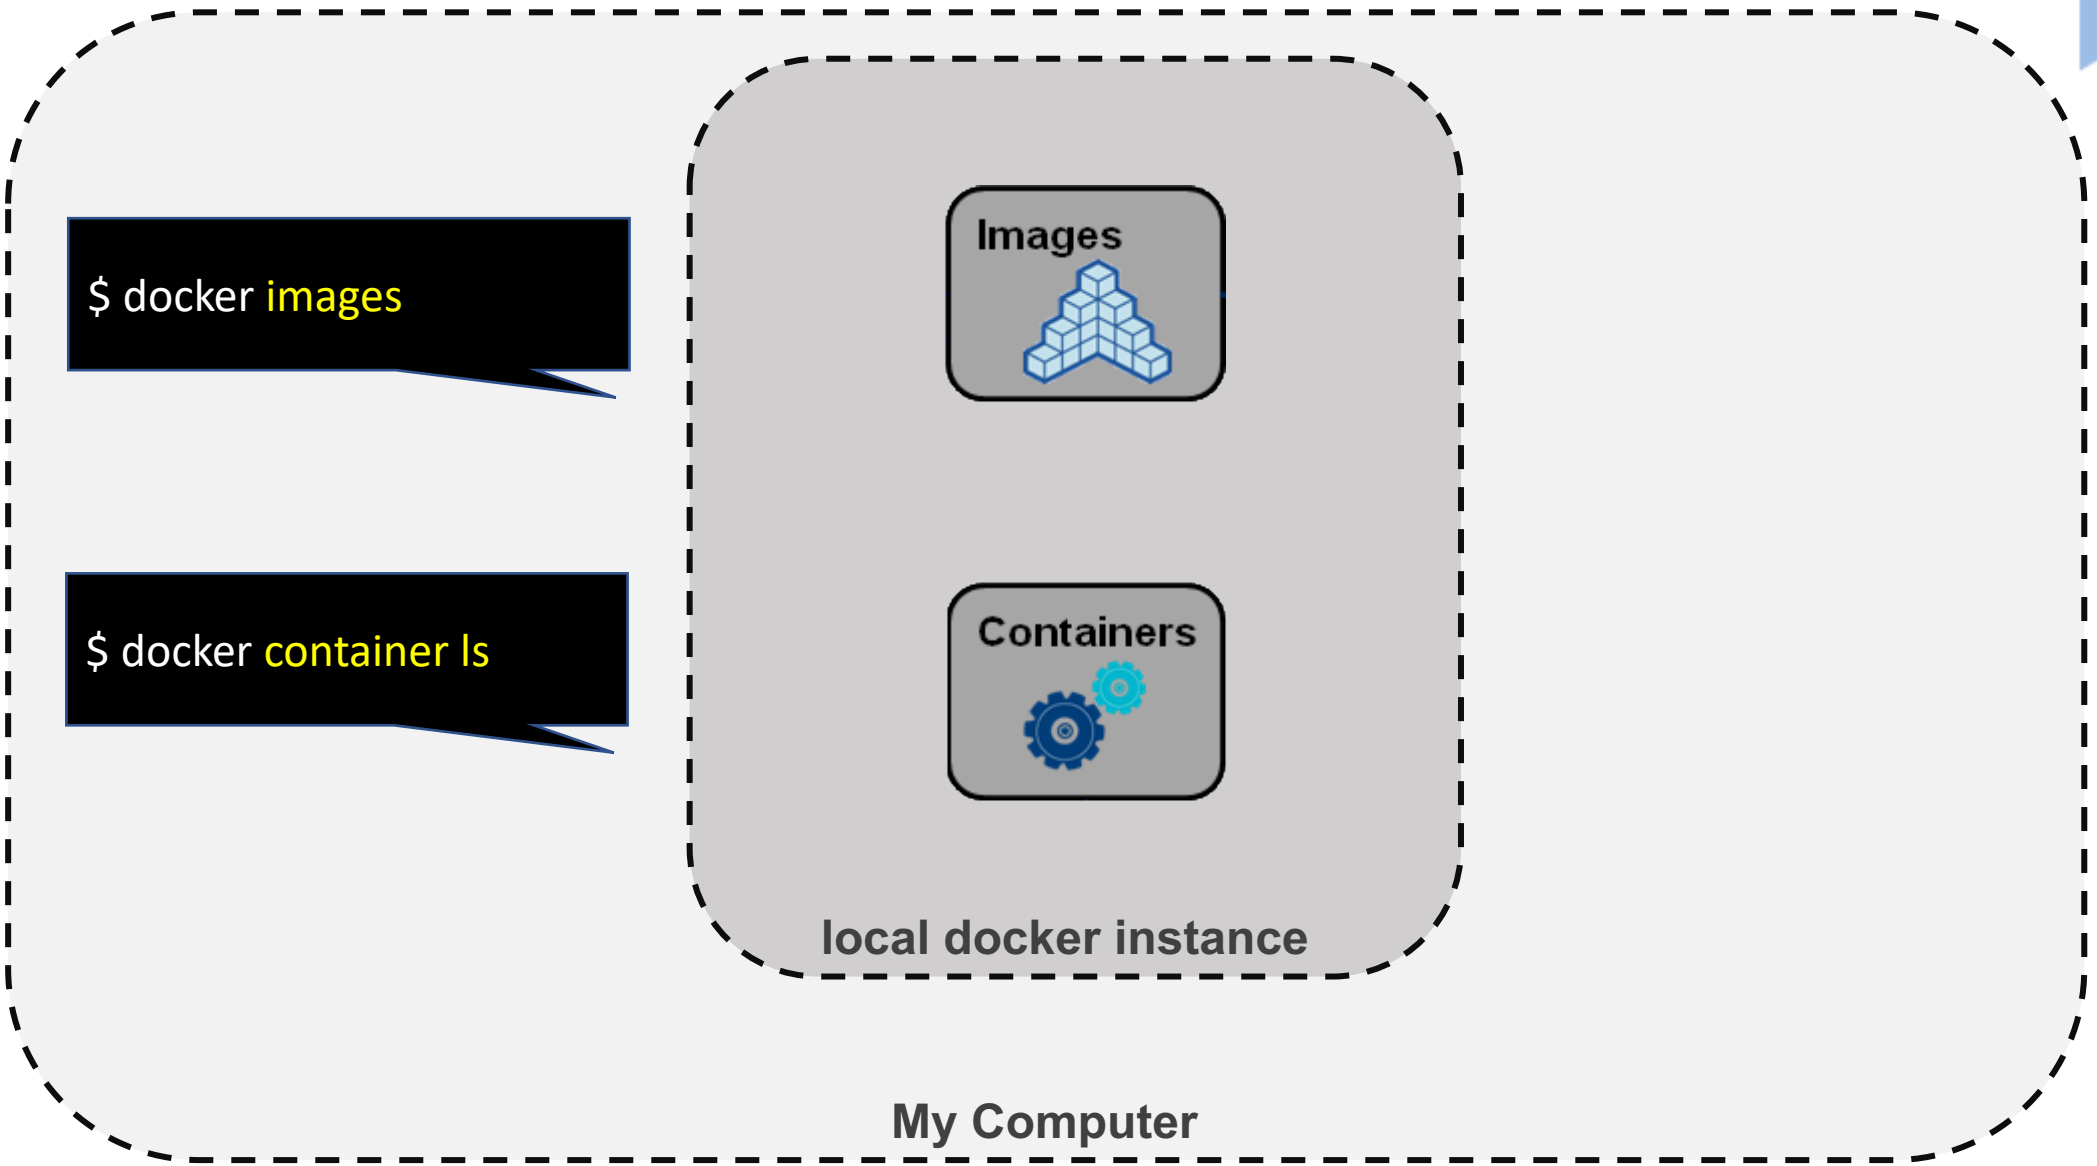
Any RUN commands you specify in the Dockerfile creates a new layer for the container. In the end when you run your container, Docker combines these layers and runs your containers. Layering helps Docker to reduce duplication and increases the re-use.

Docker Commands

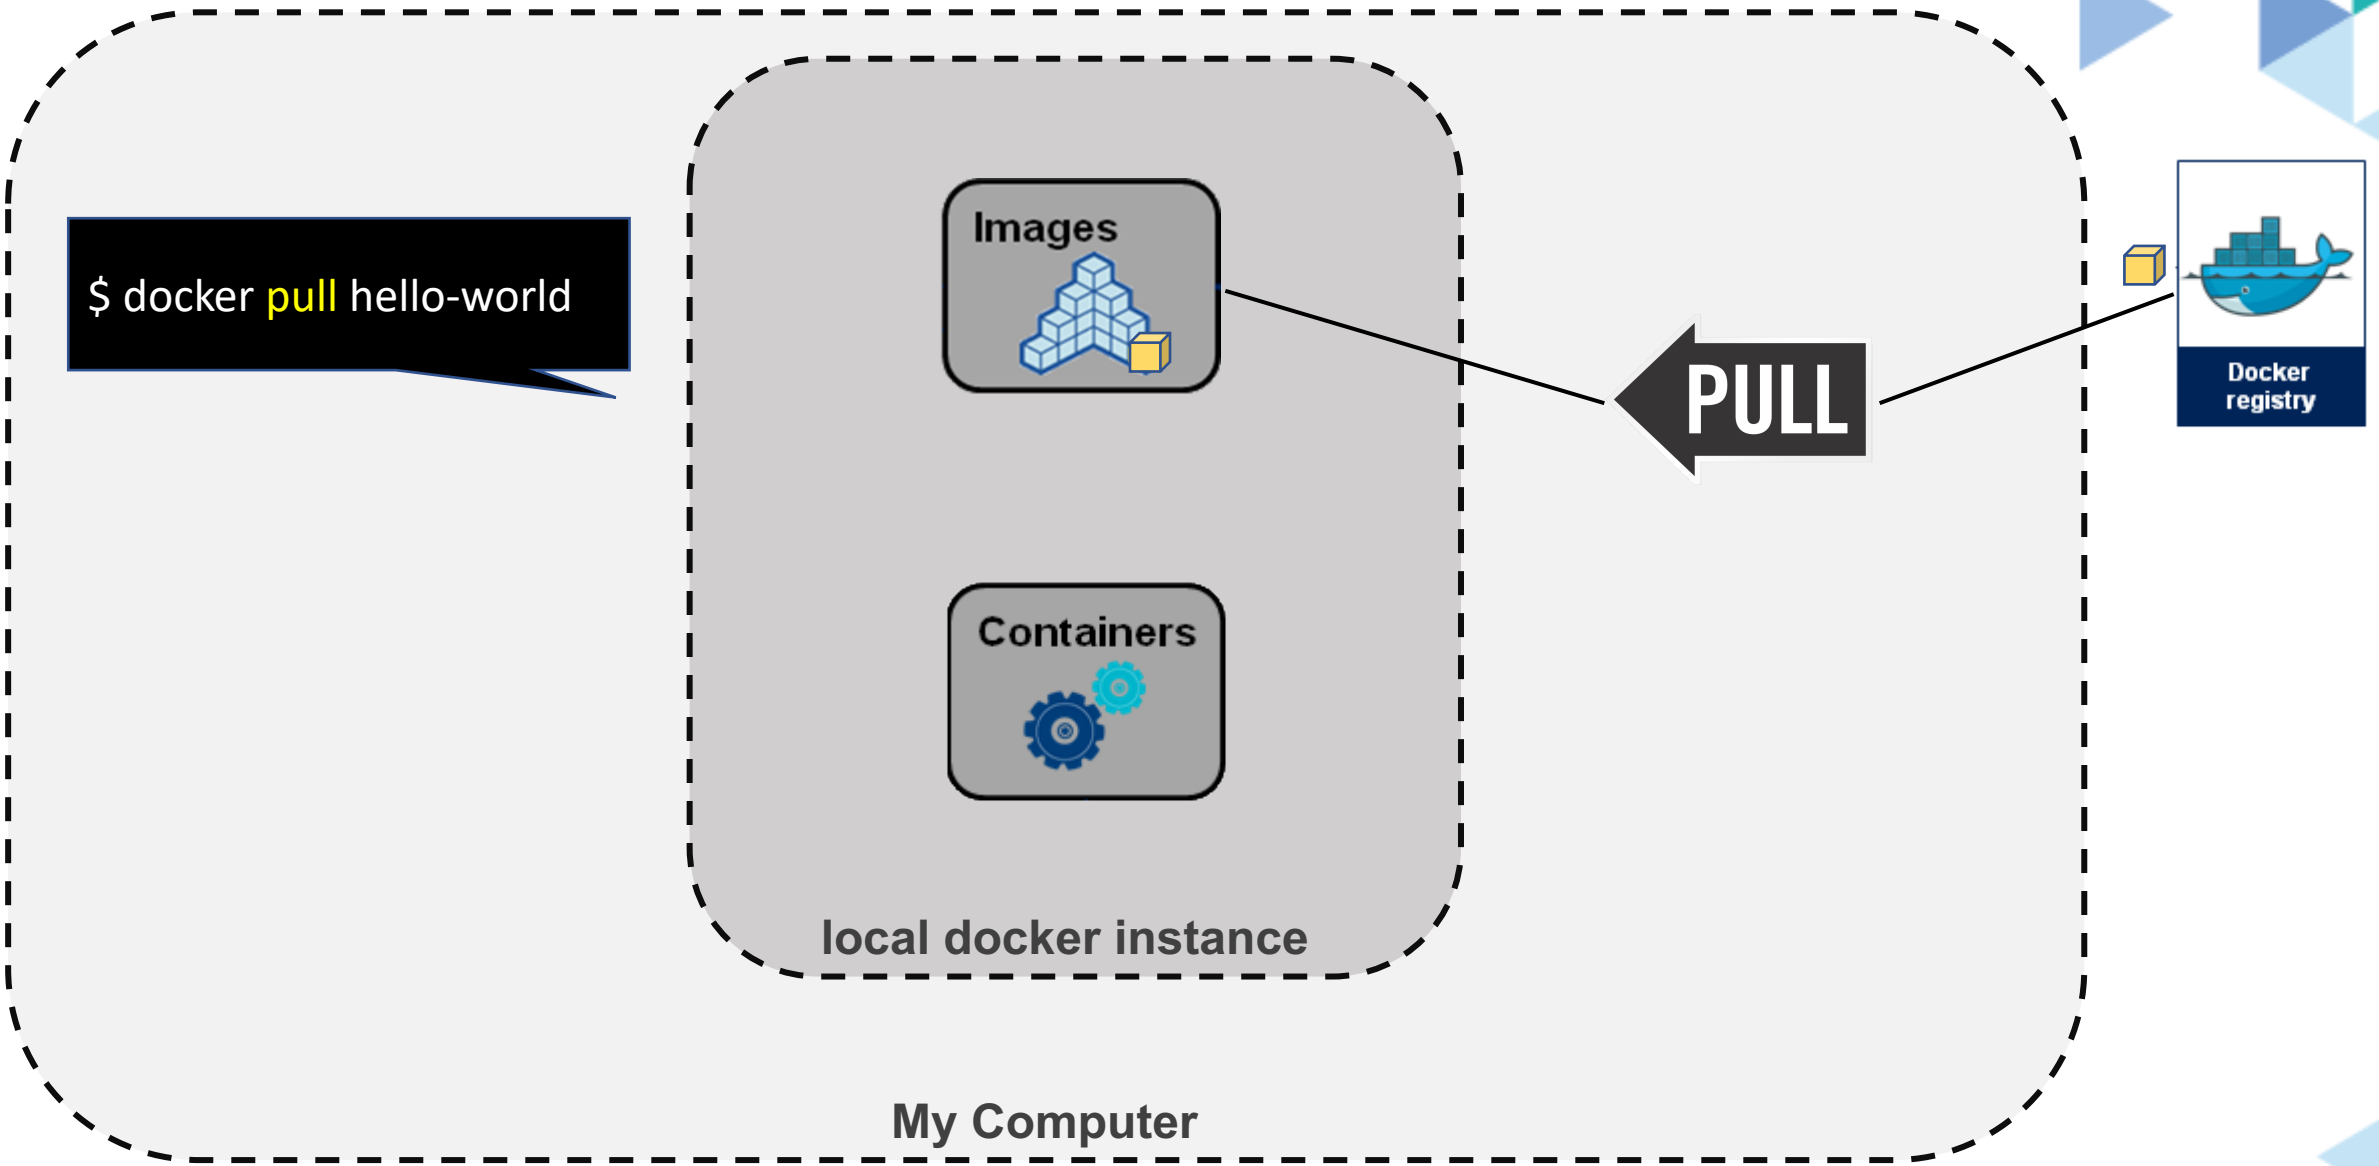
Example：

command	description
run	Run a new container from the image
start	Start a container that has stopped
stop	Stop a running container
exec	Execute a **second** command in the running container
ps	Browse the system's container
images	Browse the system image
build	Build the container from the build script Dockerfile
inspect	Check the container's system information
logs	Check the container's log

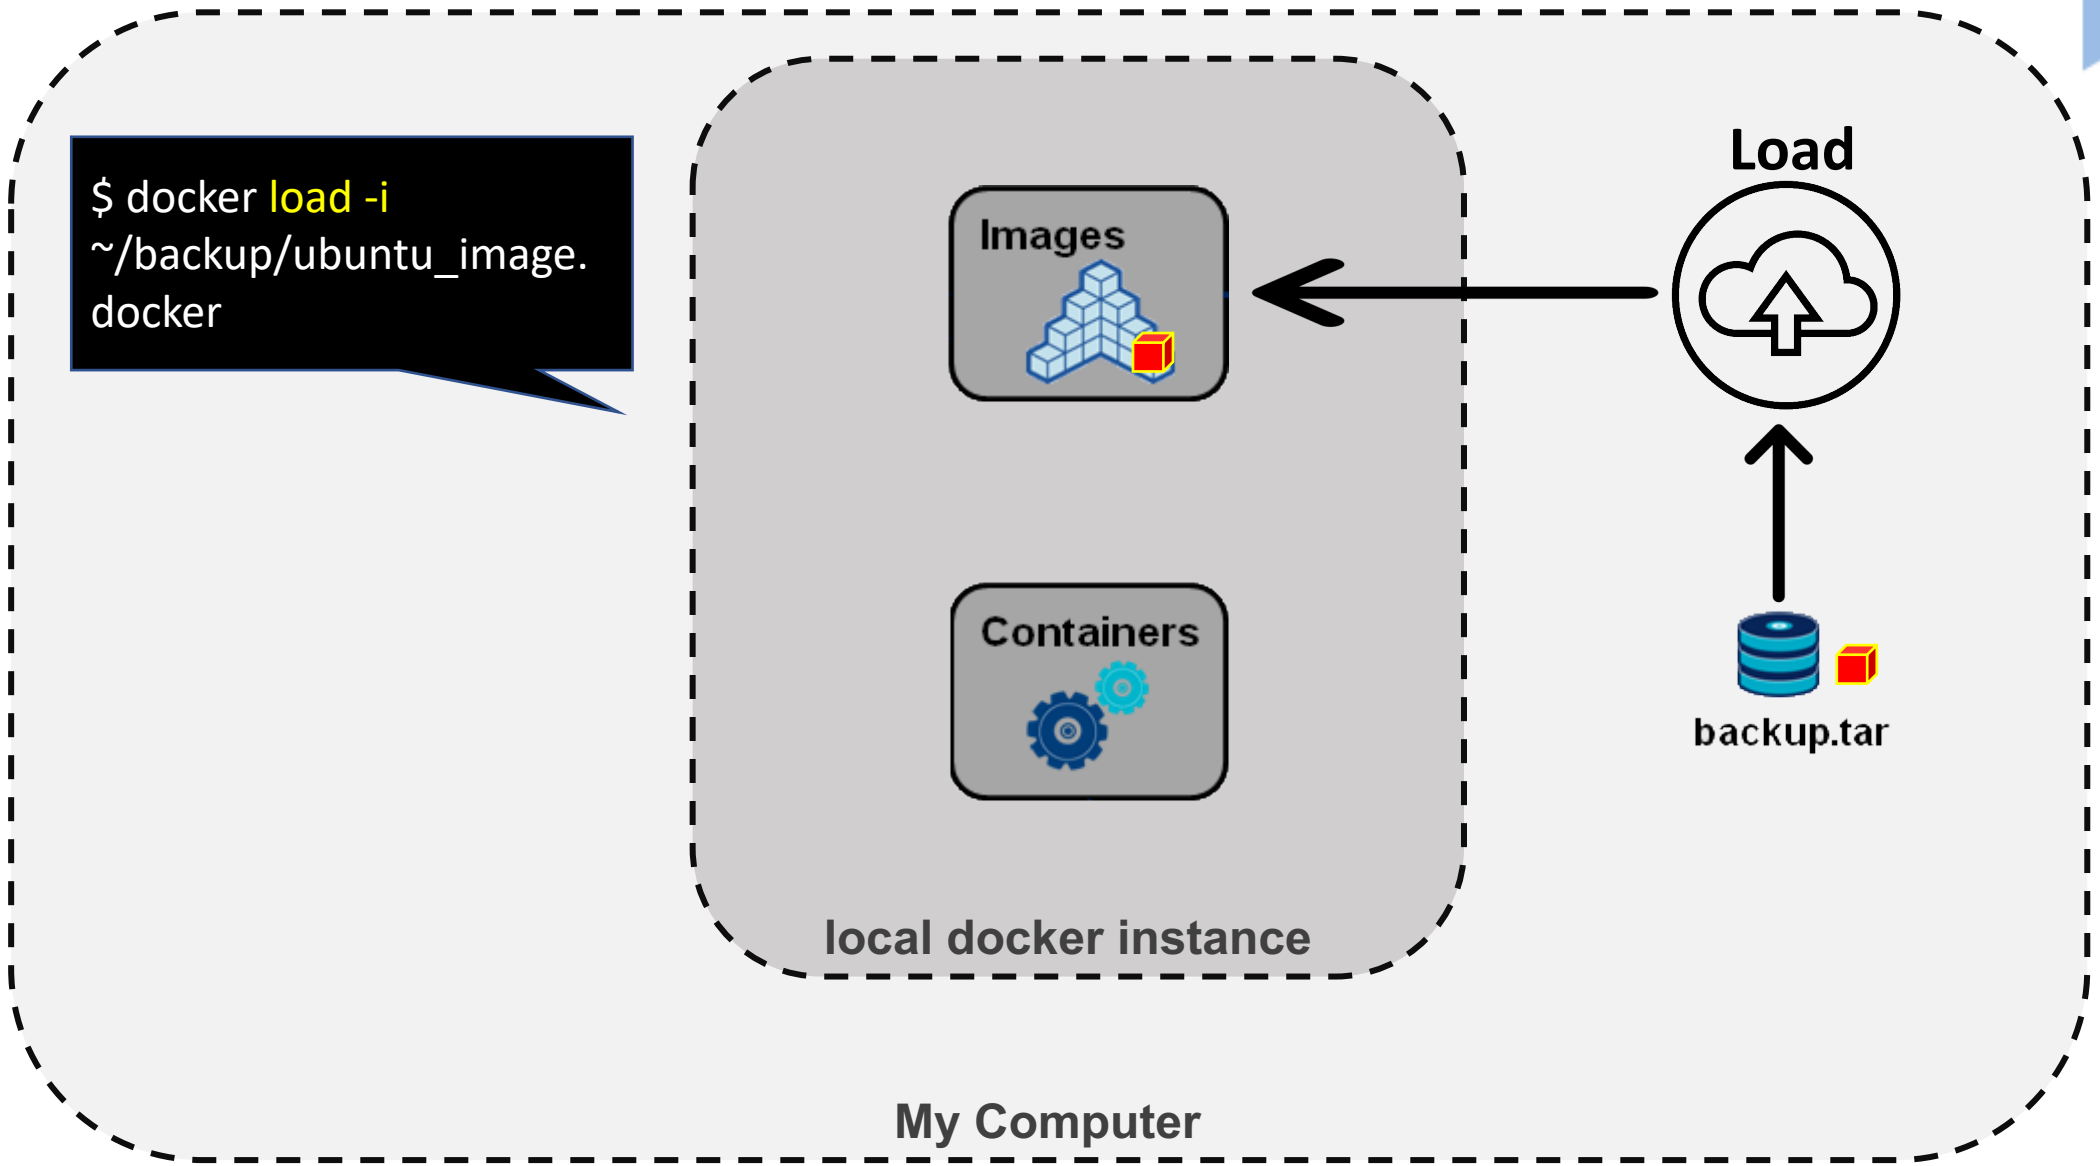
https://docs.docker.com/engine/reference/commandline/docker/



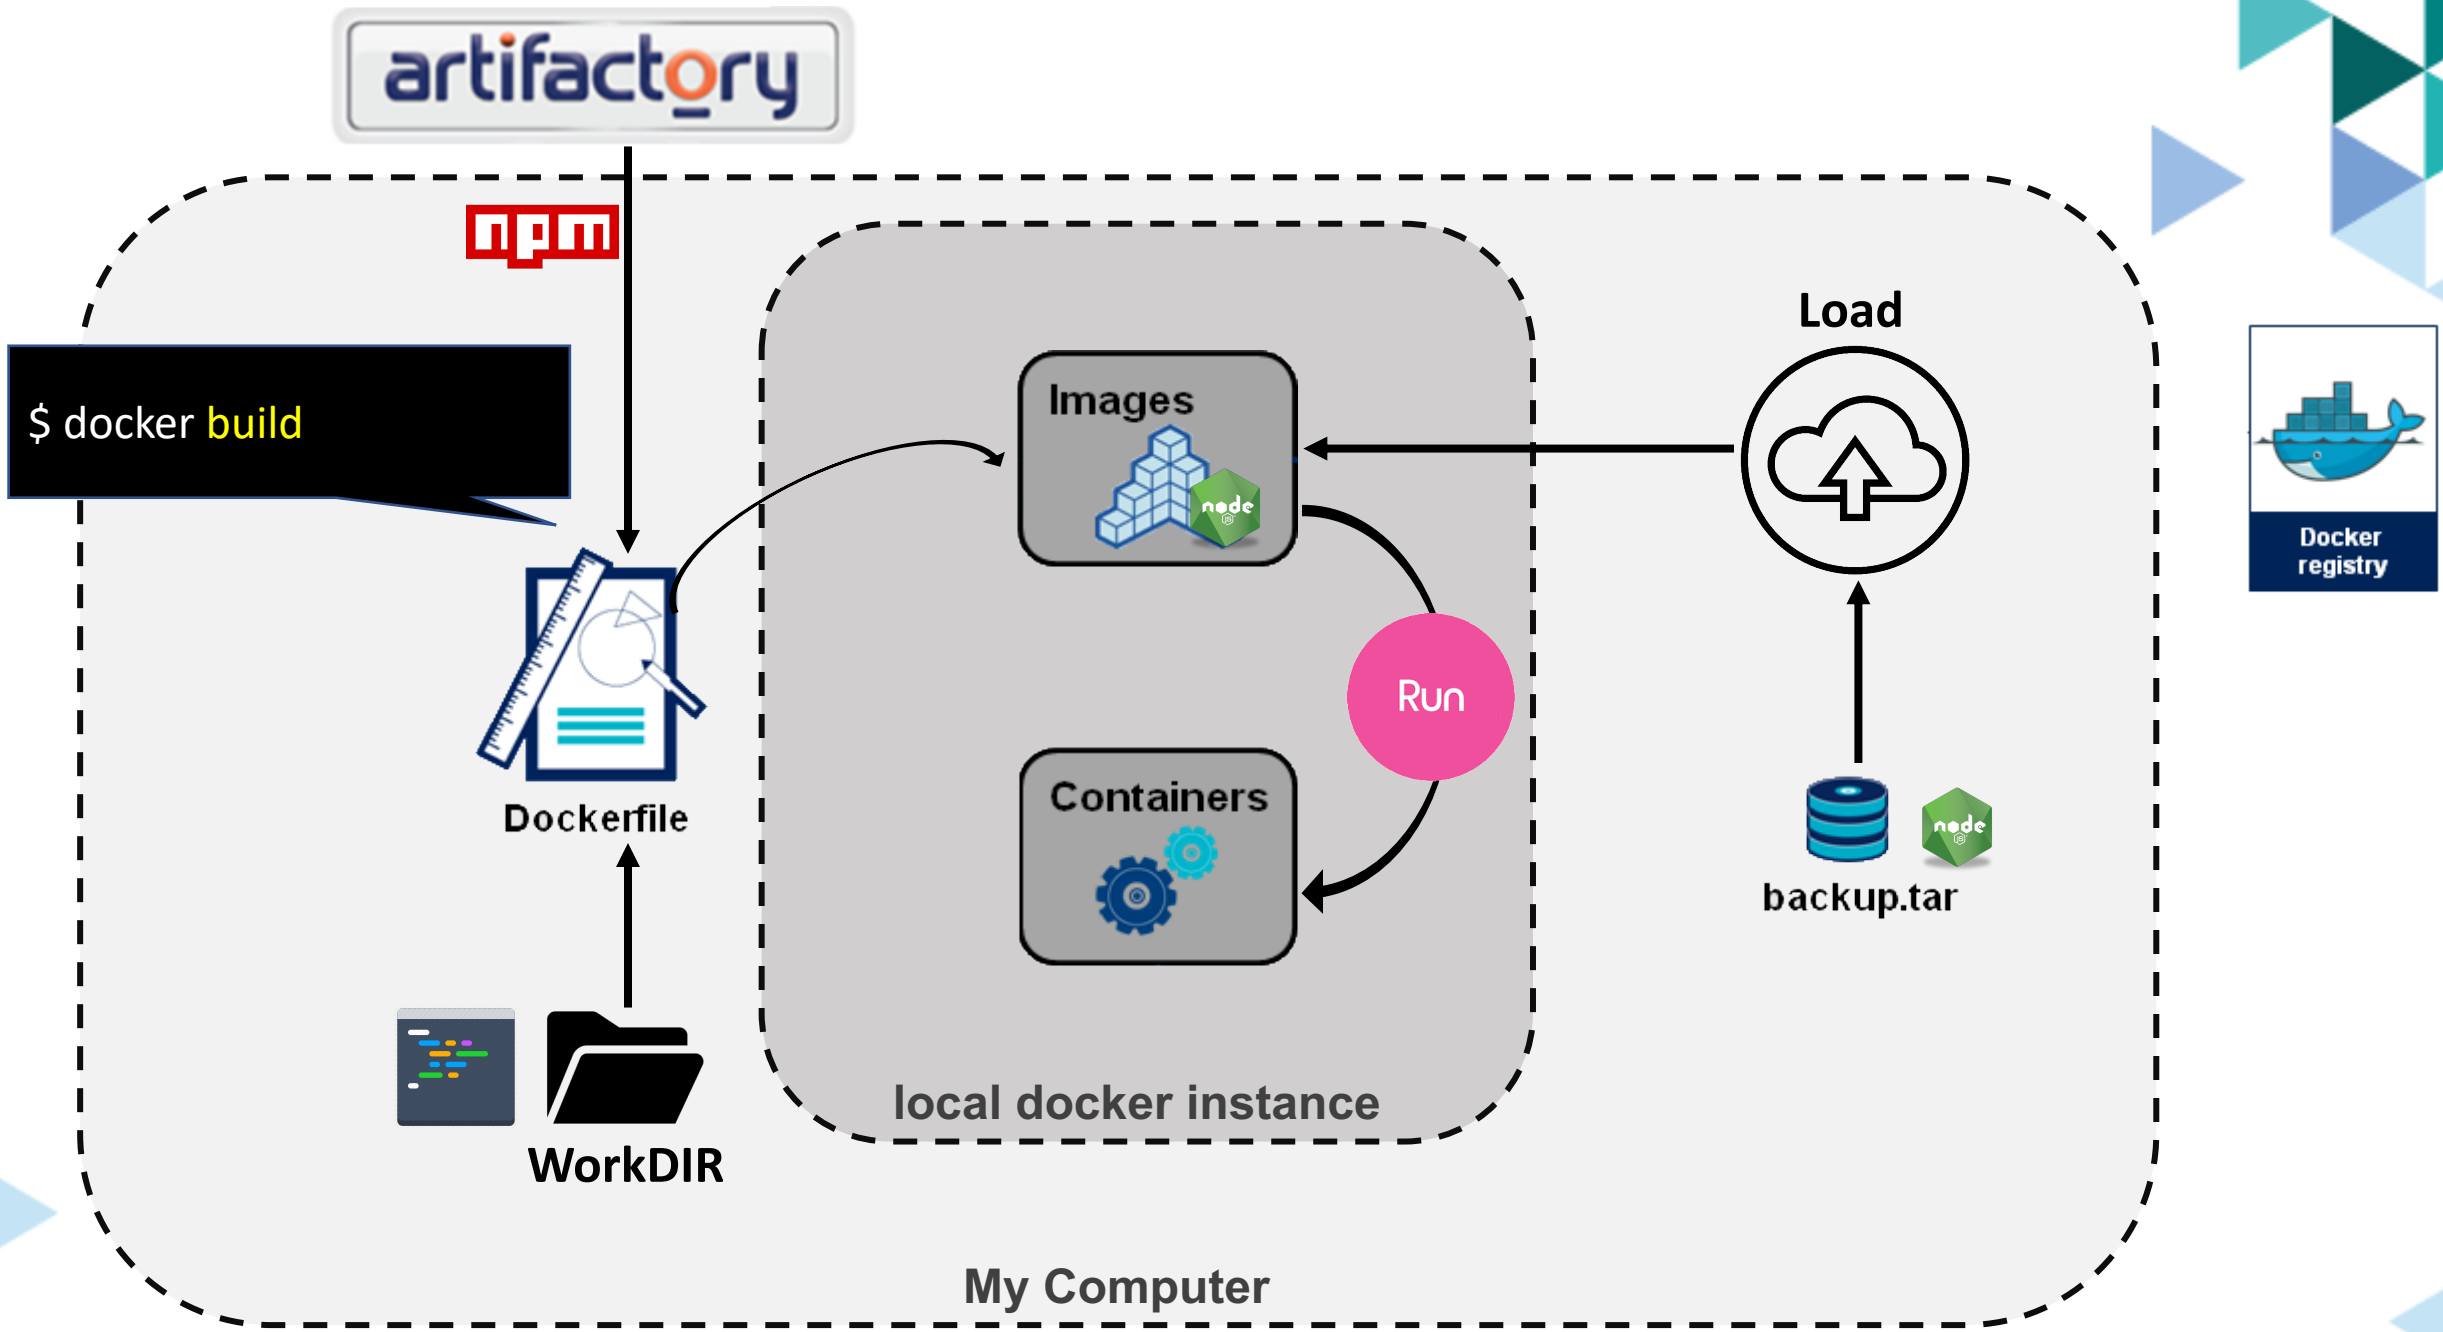
$ docker images
$ docker container ls
Images
Containers
local docker instance
My Computer
Docker registry



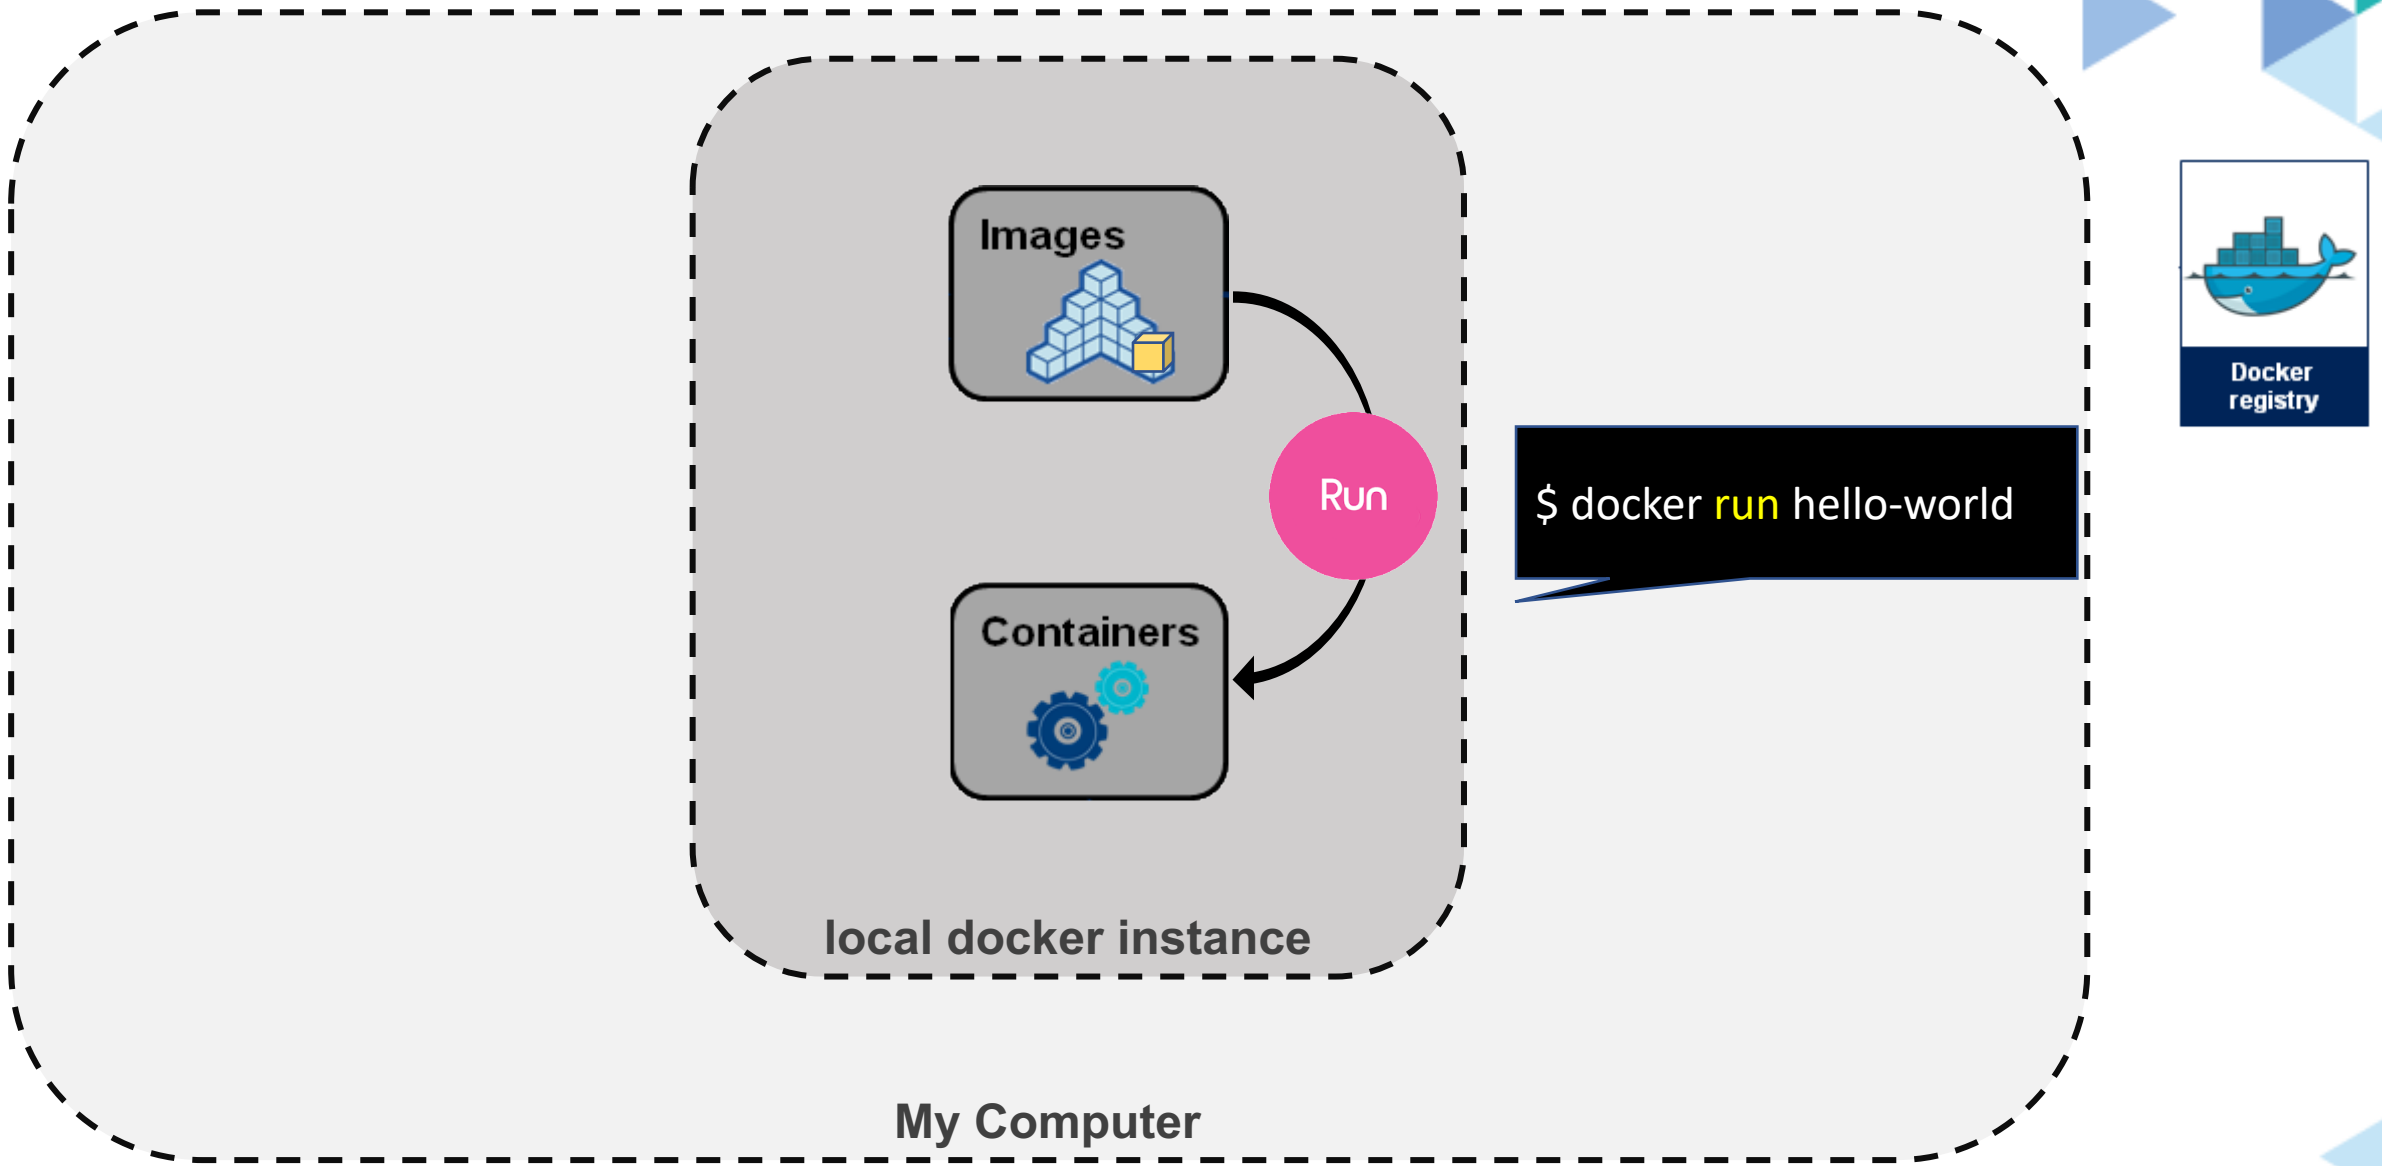
$ docker pull hello-world
Images
Containers
local docker instance
PULL
Docker registry
My Computer



$ docker load -i ~/backup/ubuntu_image.docker
Images
Containers
local docker instance
Load
backup.tar
Docker registry
My Computer



artifactory
npm
$ docker build
Dockerfile
WorkDIR
Images
Containers
Run
local docker instance
Load
backup.tar
Docker registry
My Computer



Images
Run
Containers
local docker instance
$ docker run hello-world
Docker registry
My Computer

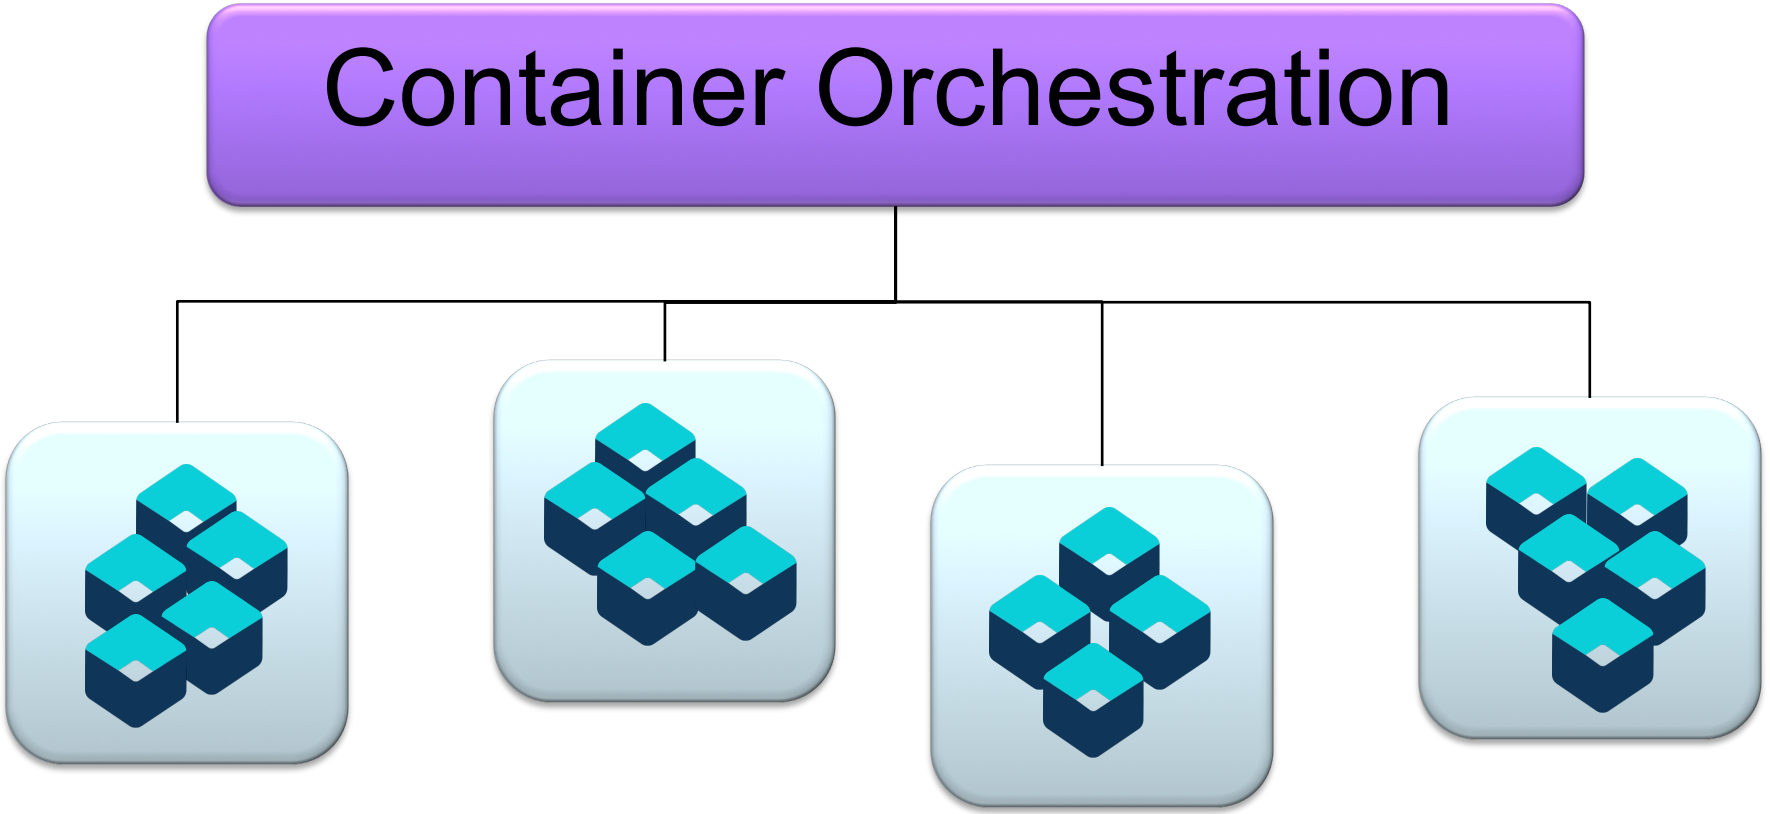
Container Orchestration !



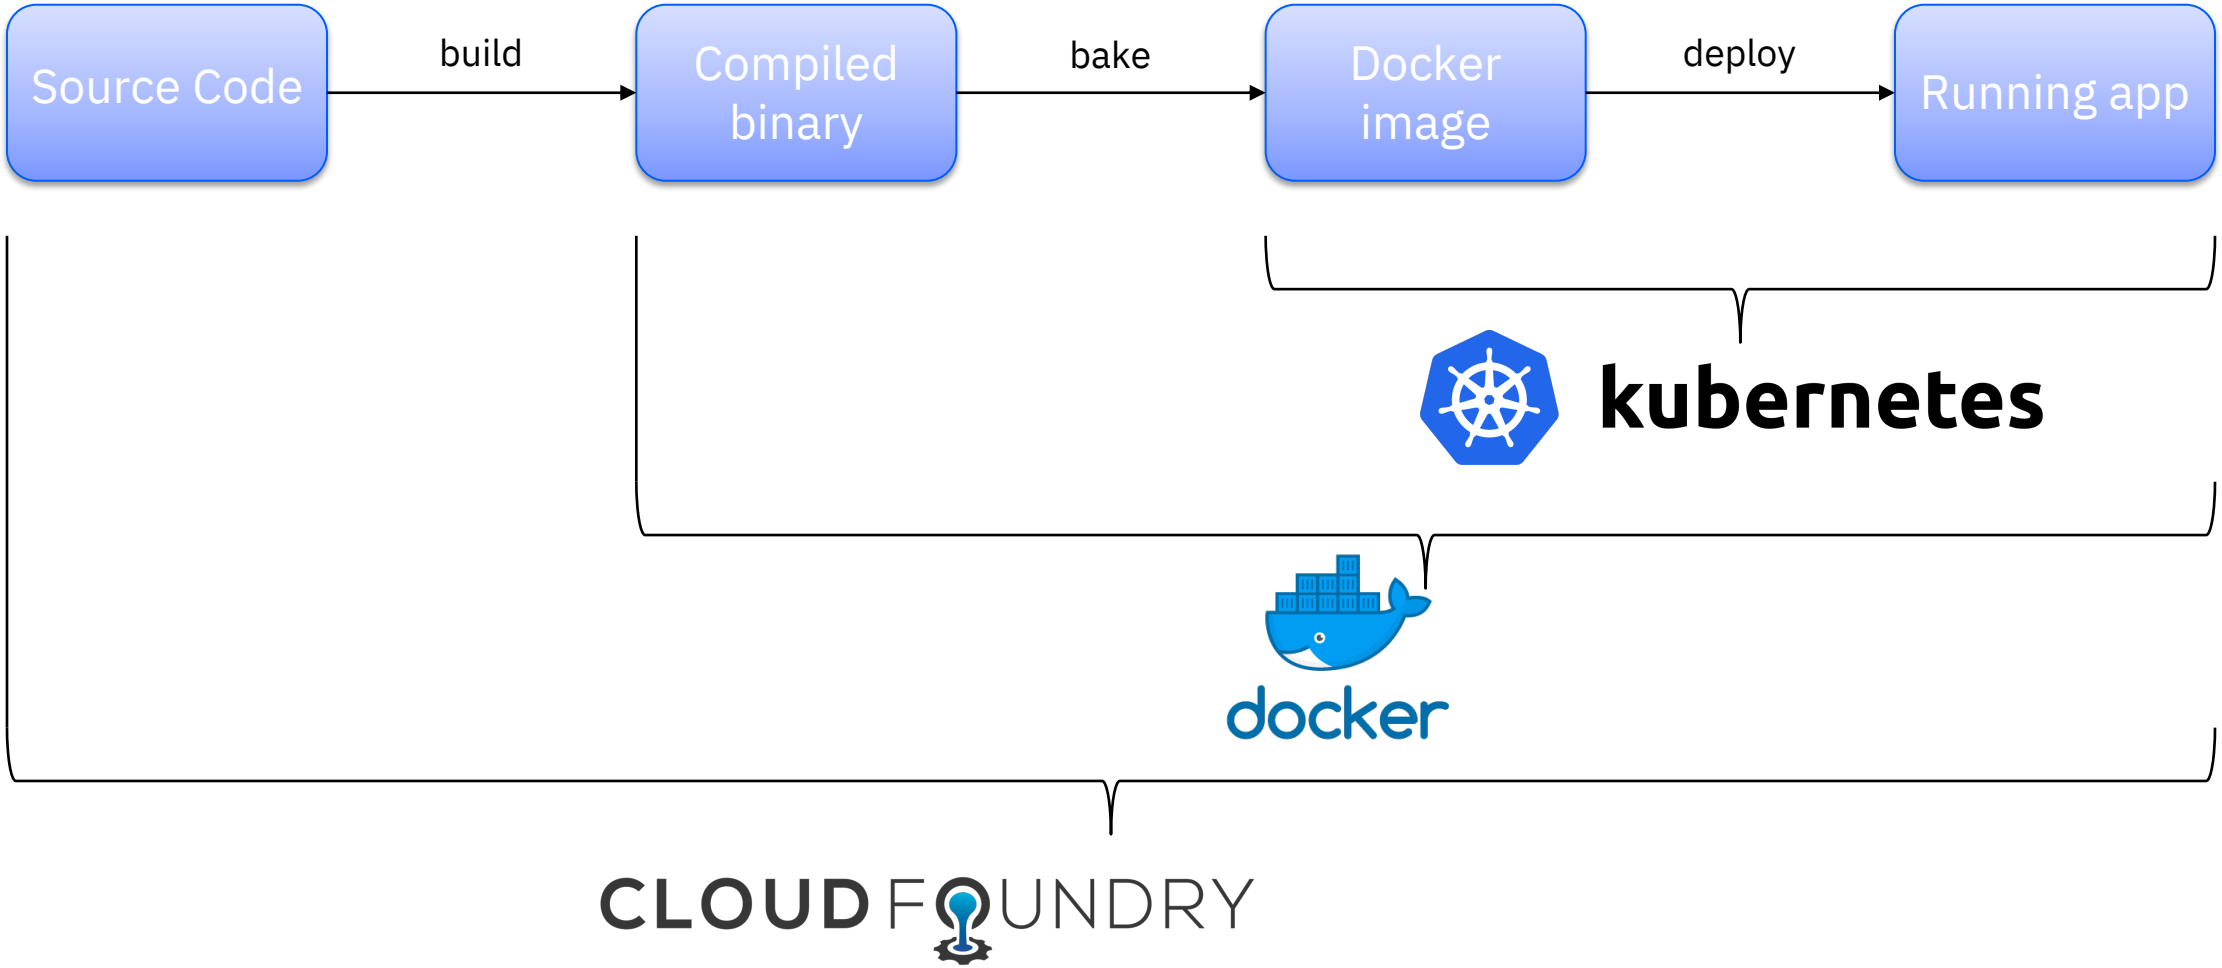
Kubernetes – Agenda

- What is Kubernetes?
- Kubernetes Architecture
- Resource Model
- Kubernetes in Action
- Kubernetes at IBM

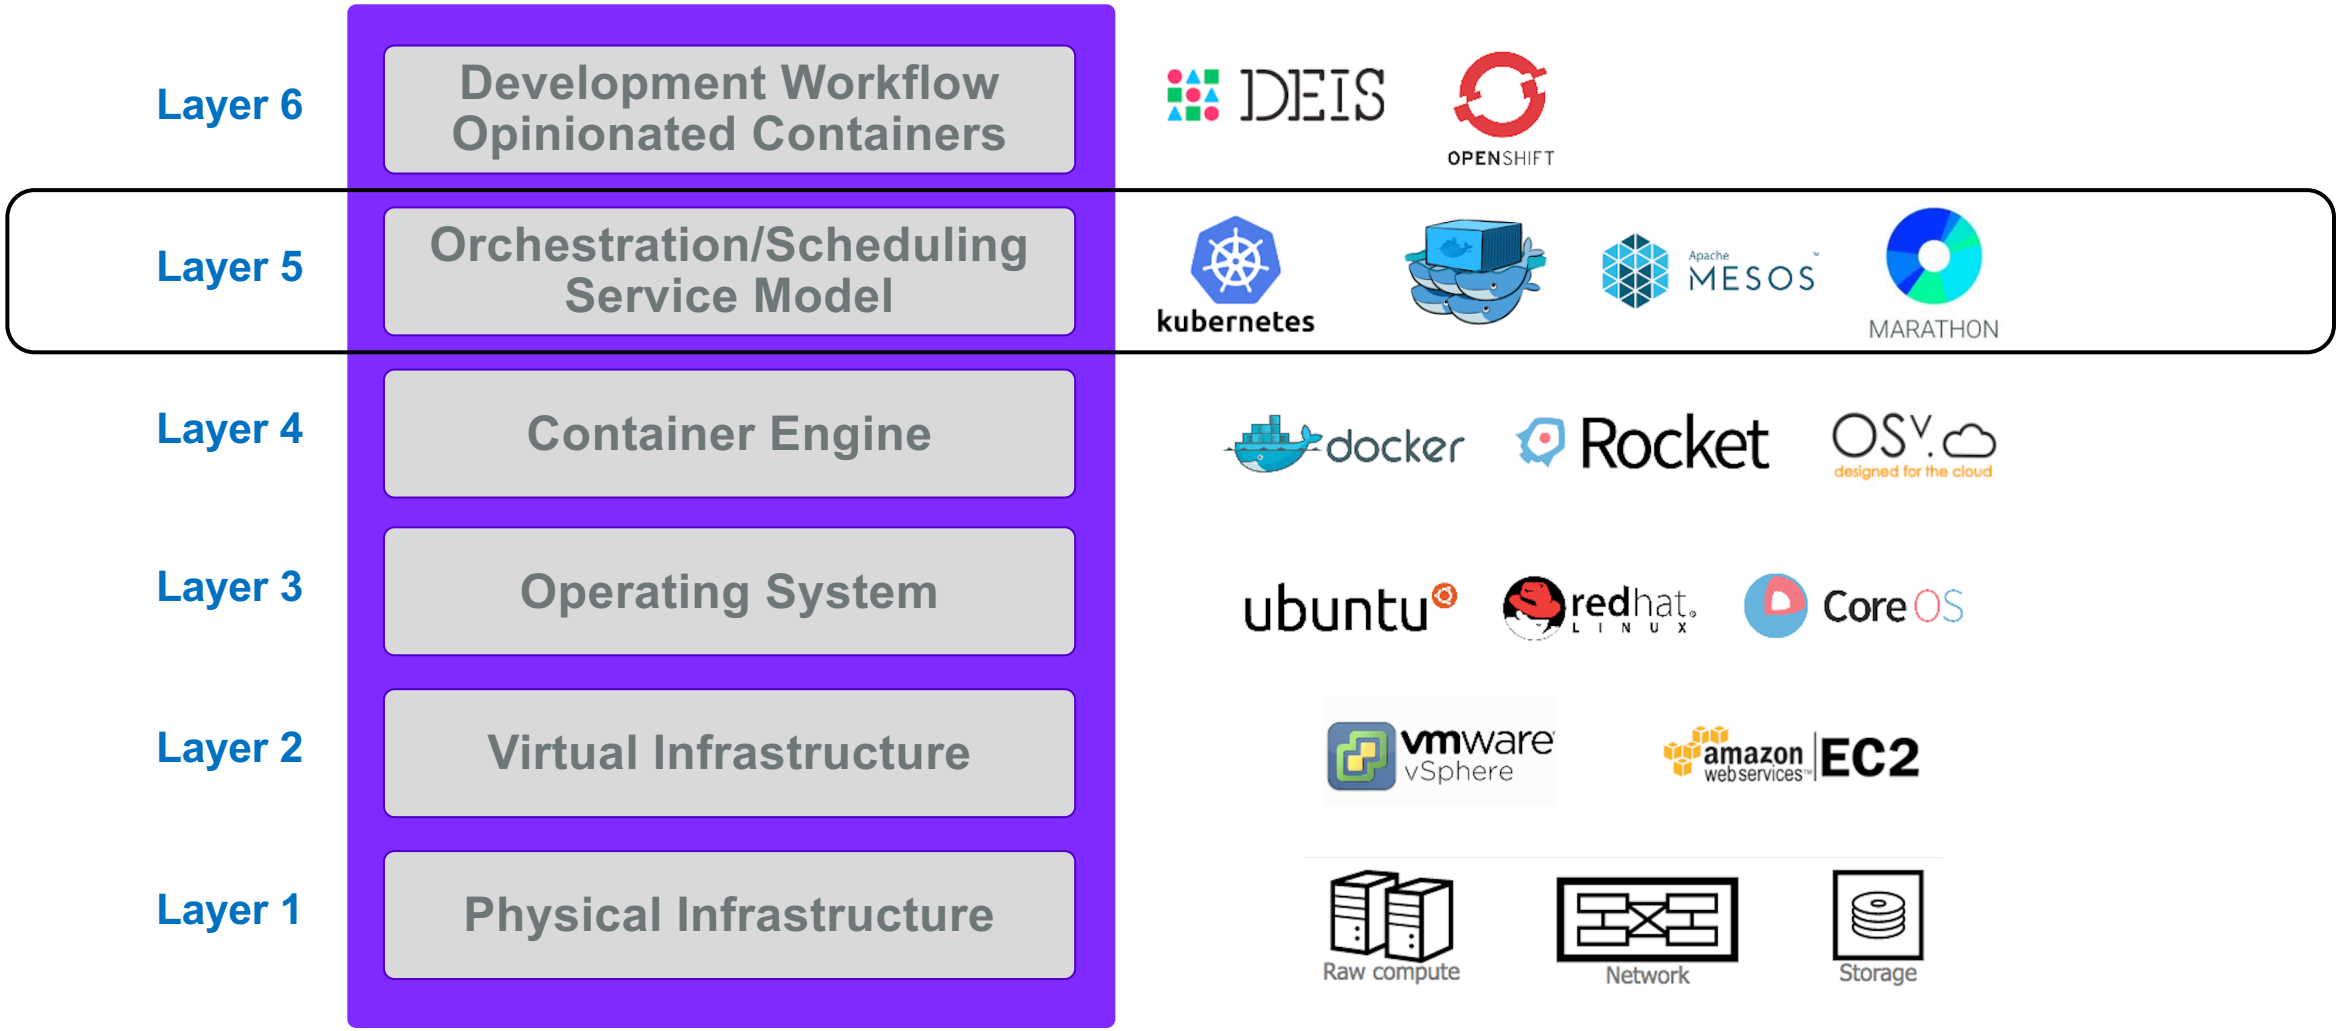
What is Kubernetes?

- **Container Orchestrator**
  - Provision, manage, scale applications
- **Manage infrastructure resources needed by applications**
  - Volumes
  - Networks
  - Secrets
  - And many many many more...
- **Declarative model**
  - Provide the "desired state" and Kubernetes will make it happen
- **What's in a name?**
  - Kubernetes (K8s/Kube): "Helmsman" in ancient Greek

Some comparisons



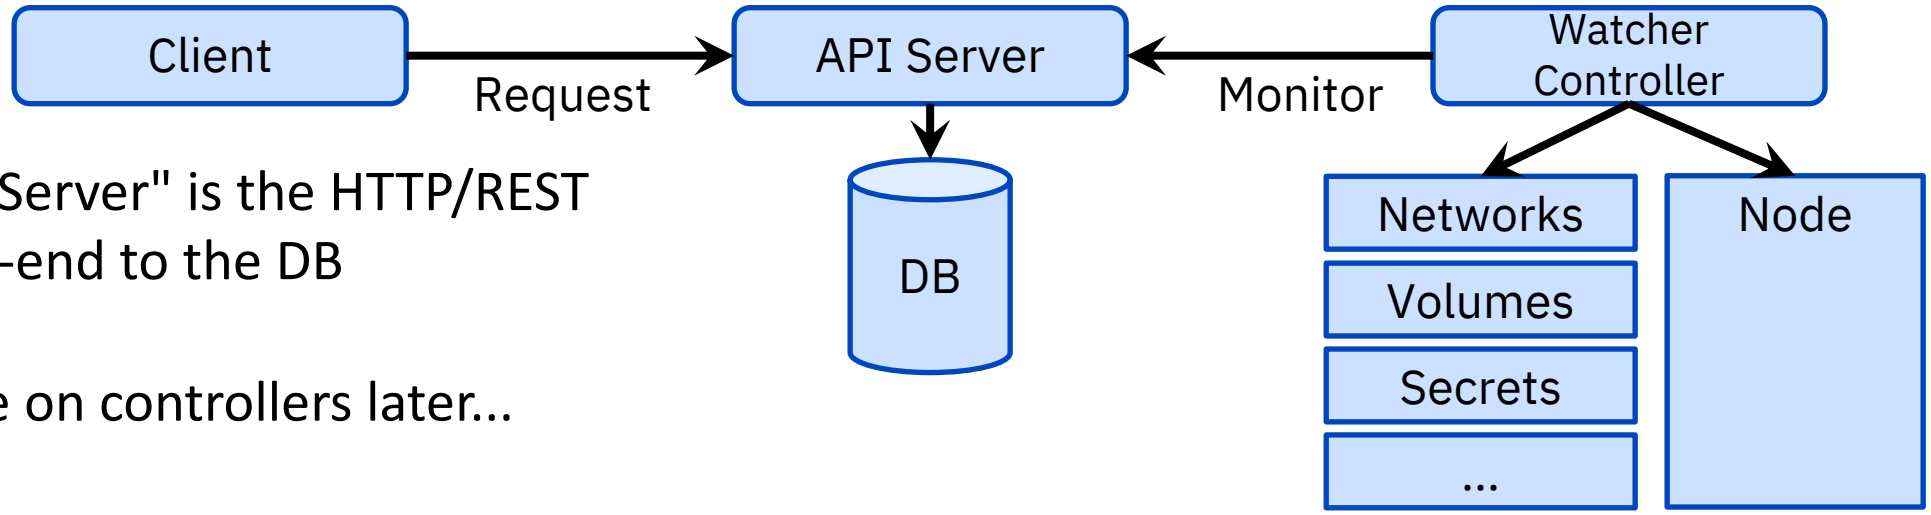
Container Ecosystem Layers



What is Kubernetes?

At its core, Kubernetes is a database (etcd).
With "watchers" & "controllers" that react to changes in the DB.
The controllers are what make it Kubernetes.
This pluggability and extensibility is part of its "secret sauce".

DB represents the user's desired state
Watchers attempt to make reality match the desired state



"API Server" is the HTTP/REST front-end to the DB

More on controllers later...

Kubernetes resource model

- A resource for every purpose

Config Maps
Daemon Sets
Deployments
Events
Endpoints
Ingress
Jobs
Nodes
Namespaces
Pods
Persistent Volumes
Replica Sets
Secrets
Service Accounts
Services
Stateful Sets, and more...

Kubernetes aims to have the building blocks on which you build a cloud native platform.

Therefore, the internal resource model **is** the same as the end user resource model.

Key Resources

Pod: set of co-located containers
- Smallest unit of deployment
- Several types of resources to help manage them
- Replica Sets, Deployments, Stateful Sets, ...

Services
- Define how to expose your app as a DNS entry
- Query based selector to choose which pods apply

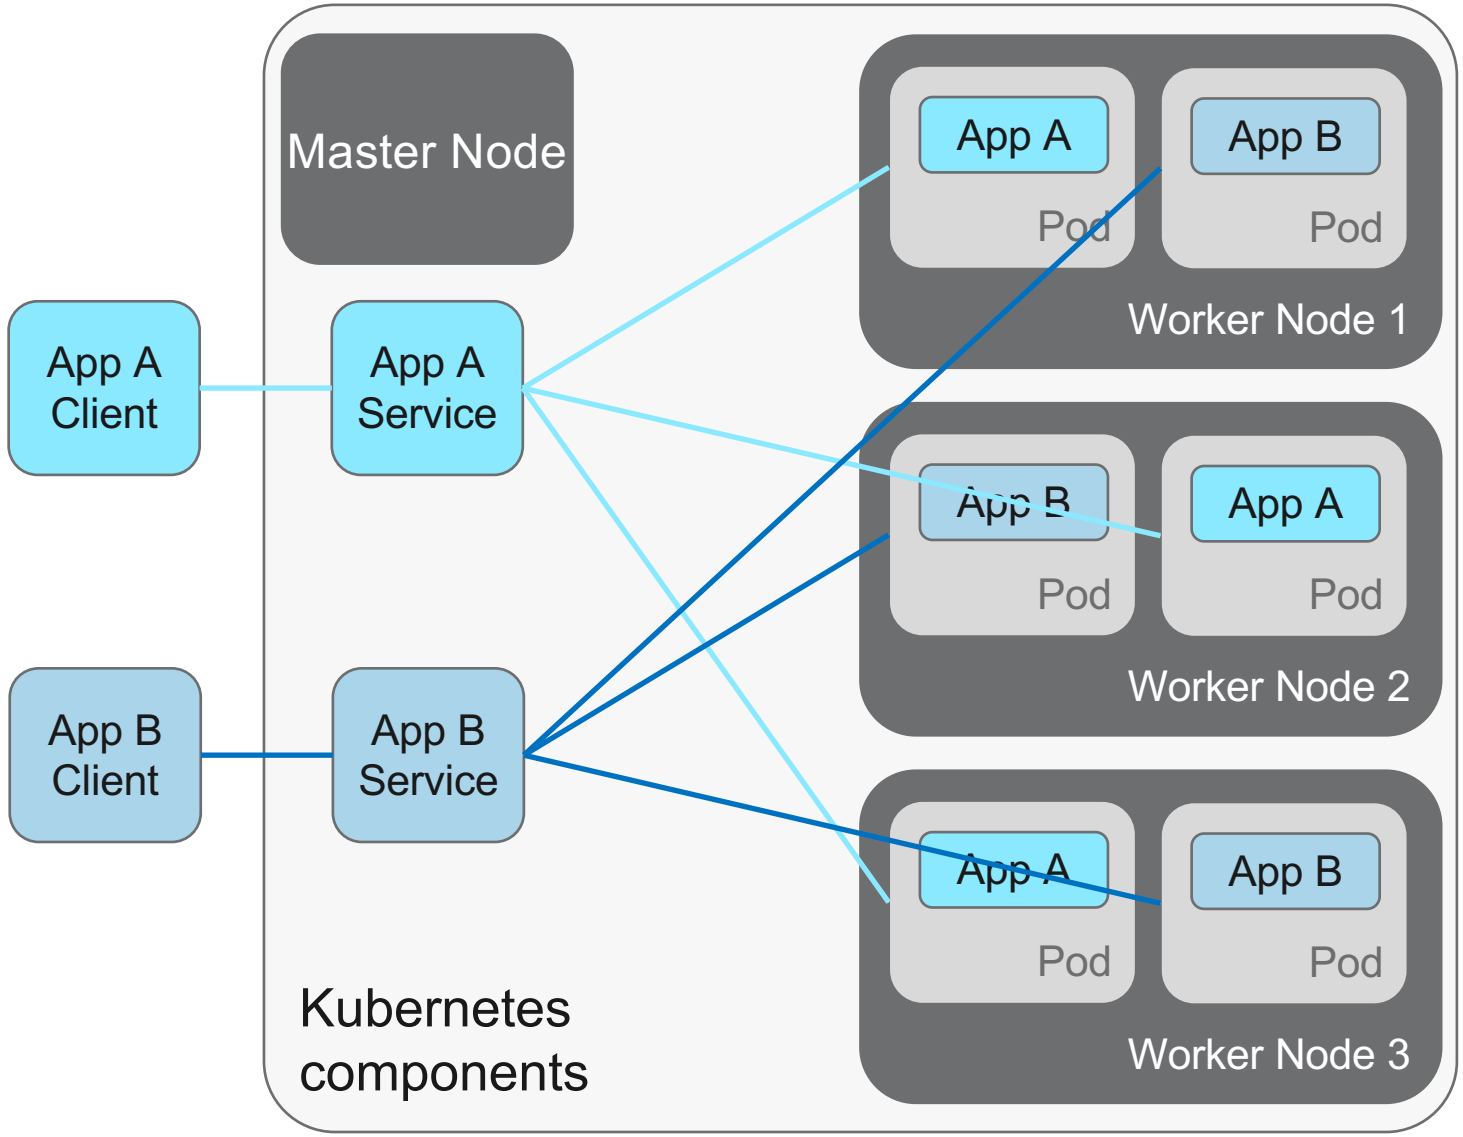
Kubernetes Architecture: How apps are accessed

Pod

- Smallest deployment unit – runs containers
- Each pod has its own IP
- Shares a PID namespace, network, and hostname

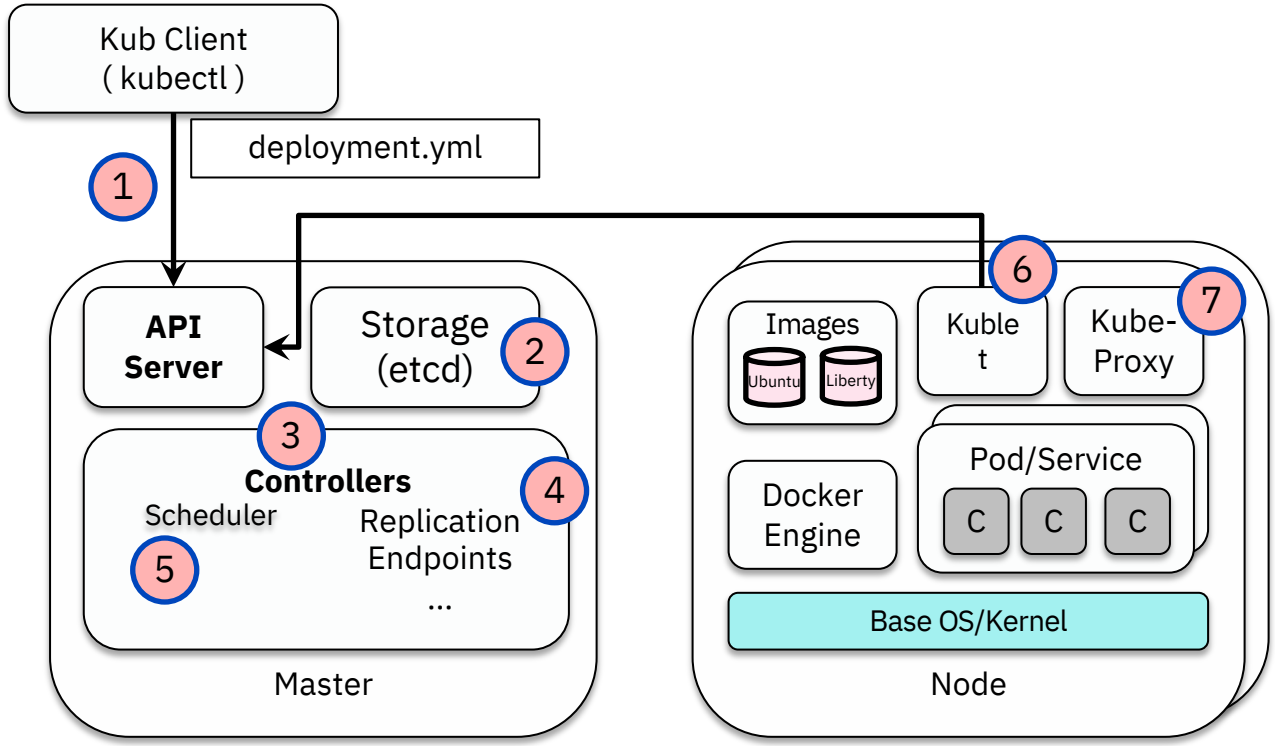
Service

- Collection of pods exposed as an endpoint
  - state and networking info propagated to all worker nodes
- Types of service exposure
  - ClusterIP – Exposes cluster-internal IP
  - NodePort – Exposes the service on each Node's IP at a static port
  - LoadBalancer – Exposes externally using a cloud provider's load balancer
  - ExternalName – Maps to an external name (such as foo.bar.example.com)



Kubernetes in Action!

1. **User via "kubectl" deploys a new application**
2. **API server receives the request and stores it in the DB (etcd)**
3. **Watchers/controllers detect the resource changes and act upon it**
4. **ReplicaSet watcher/controller detects the new app and creates new pods to match the desired # of instances**
5. **Scheduler assigns new pods to a kubelet**
6. **Kubelet detects pods and deploys them via the container runtime (e.g. Docker)**
7. **Kubeproxy manages network traffic for the pods – including service discovery and load-balancing**



Kubernetes in Action!

1. A request is sent to your app by using the public IP address of your worker node and the NodePort on the worker node.

2. The request is automatically forwarded to the NodePort service's internal cluster IP address and port. The internal cluster IP address is accessible inside the cluster only.

3. kube-proxy routes the request to the Kubernetes NodePort service for the app.

4. The request is forwarded to the private IP address of the pod where the app is deployed. If multiple app instances are deployed in the cluster, the NodePort service routes the requests between the app pods.
